

Computational Methods for Linguists

Ling 471

Olga Zamaraeva (Instructor)
Yuanhe Tian (TA)
05/18/21

Reminders and announcements

- Presentation topic suggestions
- Some of today's slides will look different
 - (I cheated and used a guest lecture I once did, as well as a Ling472 lecture I did)
 - (material probably overlaps with 472)
 - aside: LaTeX
 - maybe a demo next week

Language models
and their role in computational linguistics

Guest lecture
University of British Columbia

Olga Zamaraeva
olzama@uw.edu

Department of Linguistics, University of Washington
February 5 2019

1

Plan for today

- Smoothing
- Language models
 - N-gram
 - Neural
 - maybe spill over to Thu

Naive Bayes

a classification algorithm

- Naive Bayes relies on word counts to estimate probabilities of word sequences
 - ...and trains on labeled data
 - ...to predict labels for unseen/unlabeled data
- What's "nontrivial" about it?
 - What if you have never seen a word before?
 - Its count will be 0
 - Its probability will be 0
 - You multiply your terms by 0...
 - ...and $P(\text{entire text}) = 0!$
 - Not good!

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

<https://machinelearningmastery.com/naive-bayes-classifier-scratch-python/>

Smoothing for out-of-vocabulary” items

- Crucial technique for **all** probabilistic modeling
 - **Don't** want **zeros** in your counts, **ever!**
 - Add a **fake “unknown” word** to your **training** vocabulary
 - For every real word, **subtract** some small probability mass and **add** it to the unknown's!
 - Now in testing, every UNK gets a **non-zero** probability!
 - Why **subtract** from real words though?
 - And **how** is this related to **smoothing curves** in linear regression?

Laplacian Smoothing

$$P(w_i|class) = \frac{\text{freq}(w_i, \text{class})}{N_{\text{class}}}$$

class ∈ {Positive, Negative}

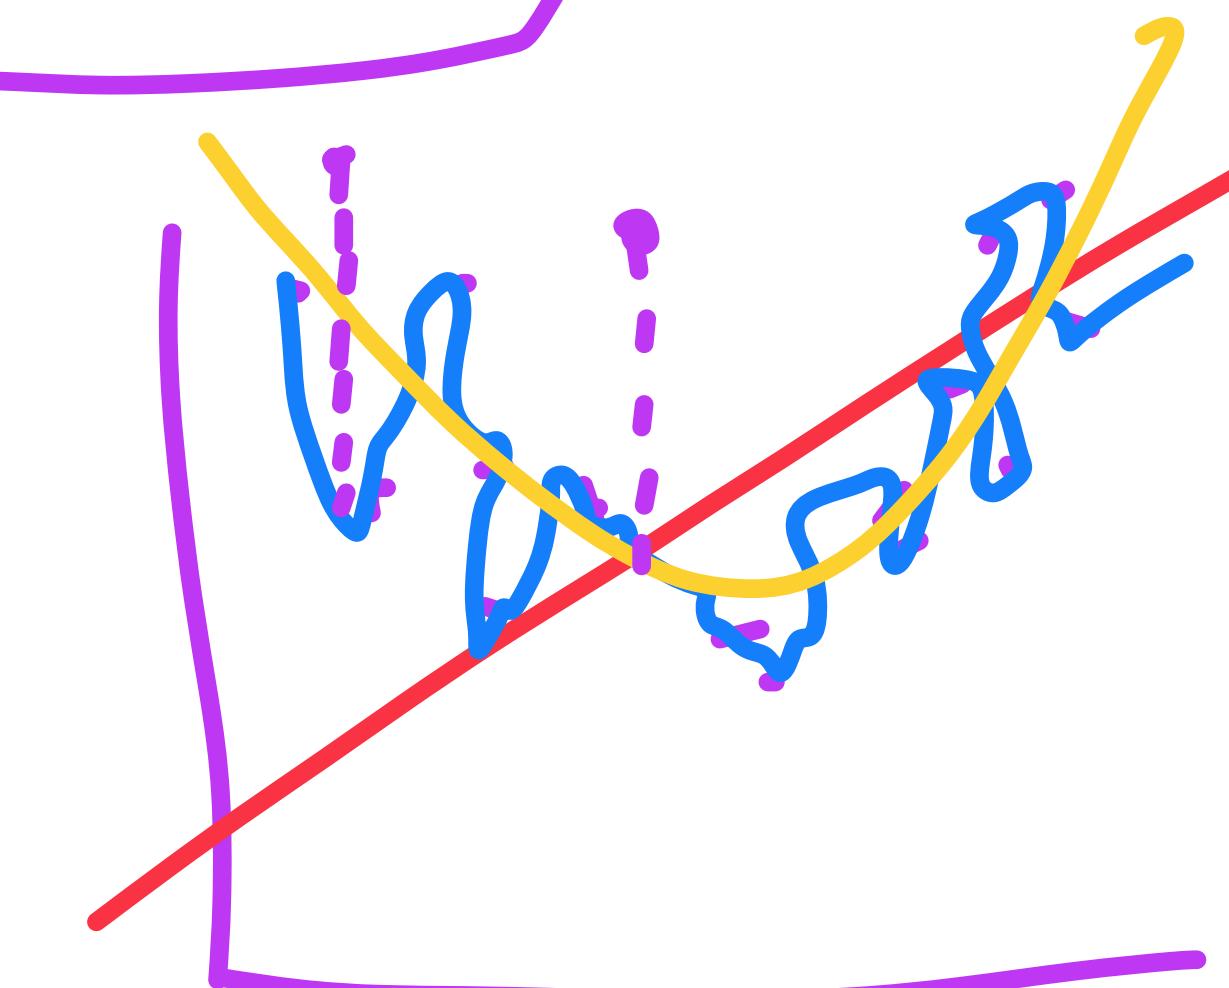

$$P(w_i|class) = \frac{\text{freq}(w_i, \text{class}) + 1}{N_{\text{class}} + V_{\text{class}}}$$

N_{class} = frequency of all words in class

V_{class} = number of unique words in class

“UNK”

Language Models

“A grammar is better, but in practice people use language models.”

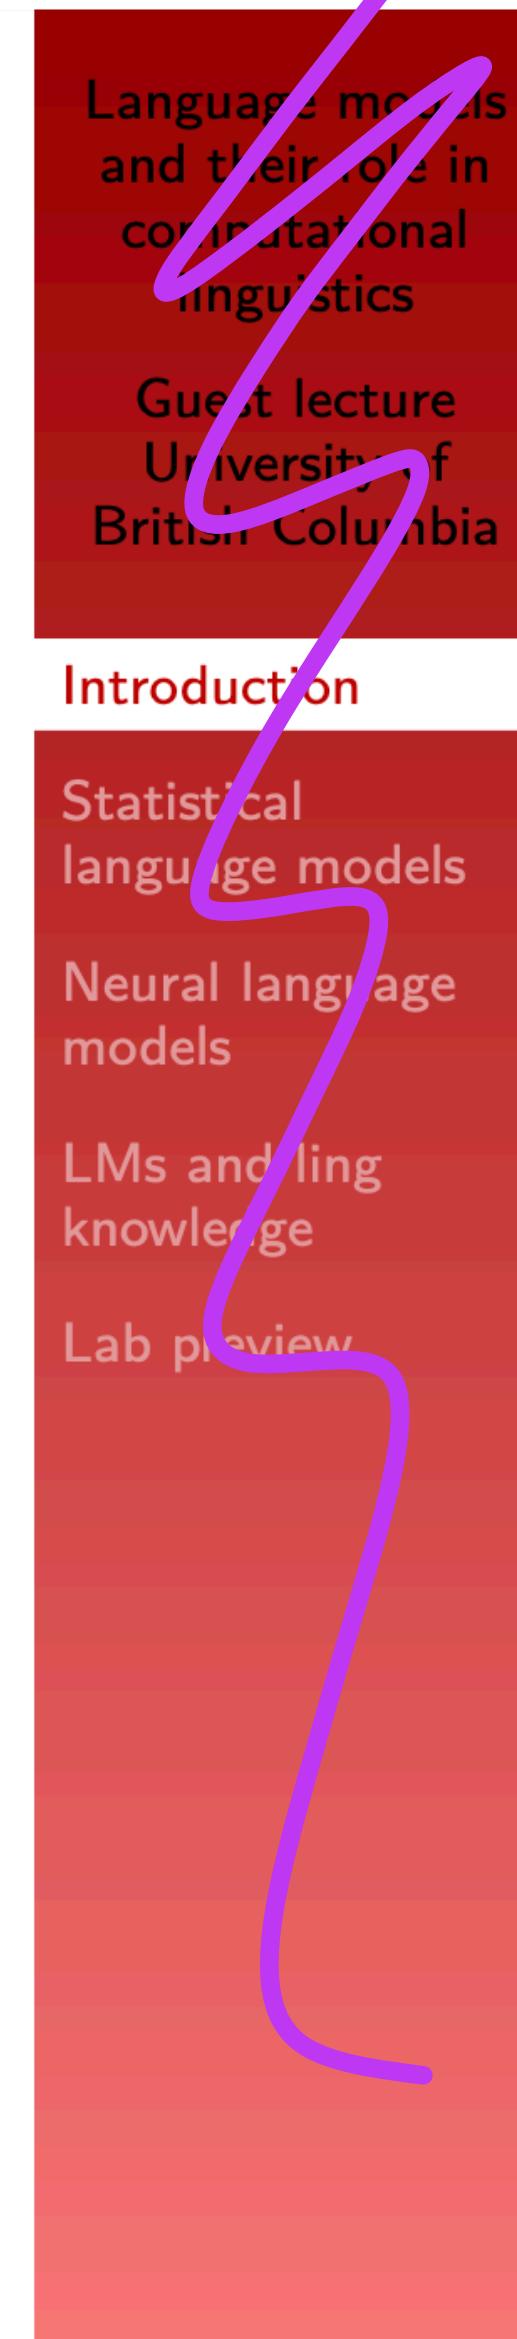

D. Jurafsky

“You are uniformly charming!” cried he, with a smile of associating and now and then I bowed and they perceived a chaise and four to wish for.

Generated by a trigram LM trained on Austen's books

“What comes out of a 4-gram model of Shakespeare looks like Shakespeare because it is Shakespeare.”

D. Jurafsky

Language Models

bigram

London is the capital of .

France

England

- ▶ Language models are programs which output the most probable word given some context
 - ▶ That's it!

unigram

N-grams: The (simplified) math behind the simplest LM

- ▶ The LM is *trained* on a corpus and can then assign probabilities to new, *test* sentences
- ▶ Train by estimating actual probabilities of word sequences from actual corpora
- ▶ E.g. what probability will a LM trained on corpus TC assign to the sentence:

“*London is the capital of England*”

- ▶ In corpus TC, how many times did we see *England* after *London is the capital of*?

London is the capital of England

- ▶ What we'd like to calculate:

$$\frac{C(\text{London}, \text{is}, \text{the}, \text{capital}, \text{of}, \text{England})}{C(\text{London}, \text{is}, \text{the}, \text{capital}, \text{of})}$$

5 grams

- ▶ In some cases, it is possible (using e.g. the web)
- ▶ But in most cases, we'd never find a corpus big enough

- Language is very creative!

Markov assumption

Andrey Markov (1856-1922)

(Not-so-fun-fact: In 1908, Markov was fired from the University for refusing to spy on his students)

- ▶ Markov assumption: The probability of a given word only depends on **a few** previous words, not the entire sequence
- ▶ *Approximate* the history given the last (few) word(s)

$$P(w_n | w_1^{n-1}) \approx P(w_n | w_{n-1})$$

L is + c of E
w₁ w₂ | w_n

N-grams and Naive Bayes

- What's the relationship?
 - N-grams are not a classifier
 - they are good for text generation
 - and for estimating word probabilities
 - ...which in turn is what Naive Bayes needs!
 - Naive Bayes is a classifier which uses word frequencies
 - it can use unigram, bigram, n-gram

A photograph of a whiteboard with a hand-drawn formula for Naive Bayes probability. The formula is written in blue marker and reads: $P(A|B) = \frac{P(B|A)P(A)}{P(B)}$. The whiteboard has a grid pattern and some faint markings from previous work.

<https://machinelearningmastery.com/naive-bayes-classifier-scratch-python/>

N-gram: bigger N means closer approximation

- ▶ $P(\text{England} \mid \text{London is the capital of})$
 - ▶ $P(\text{England} \mid \text{of})$ – **bigram**
 - ▶ $P(\text{England} \mid \text{capital of})$ – **trigram**
 - ▶ $P(\text{England} \mid \text{the capital of})$
 - ▶ $P(\text{England} \mid \text{is the capital of})$

N-gram: bigger N means closer approximation

Consider *generating* from such models:

- ▶ $P(\text{Horatio} \mid \text{Alas, poor Yorick! I knew him, })$
 - ▶ $P(\text{Horatio} \mid \text{him,})$ – **bigram**
 - ▶ $P(\text{Horatio} \mid \text{knew him,})$ – **trigram**
 - ▶ $P(\text{Horatio} \mid \text{I knew him,})$
 - ▶ $P(\text{Horatio} \mid \text{Yorick! I knew him,})$
 - ▶ $P(\text{Horatio} \mid \text{poor Yorick! I knew him,})$

Small N = “silly” model, big N = rigid model (how interesting is it to generate exact strings from Shakespeare’s *Hamlet*?)

Interim summary

- ▶ N-grams are simple, easily implementable, trainable on small amounts of data
 - ▶ but, are either silly (approximate the corpus poorly) or start generating Shakespeare (approximate too much)
- ▶ Today, NLP mostly uses more flexible *neural* LMs

Neural language models

Neural* language models

- ▶ Predict the word given context (or vice versa)
- ▶ Generalize over contexts, are more “creative” than n-grams:
 - ▶ Learn which words occur in similar contexts
 - ▶ It is possible to build a neural model that creates representations for unknown words “on the fly”**
- ▶ But:
 - ▶ Are more complex to train
 - ▶ Require lots of training data to start working well
 - ▶ Learn the training data biases

*These are *simplified* neural architectures

**Not the same architecture as in the lecture

XOR

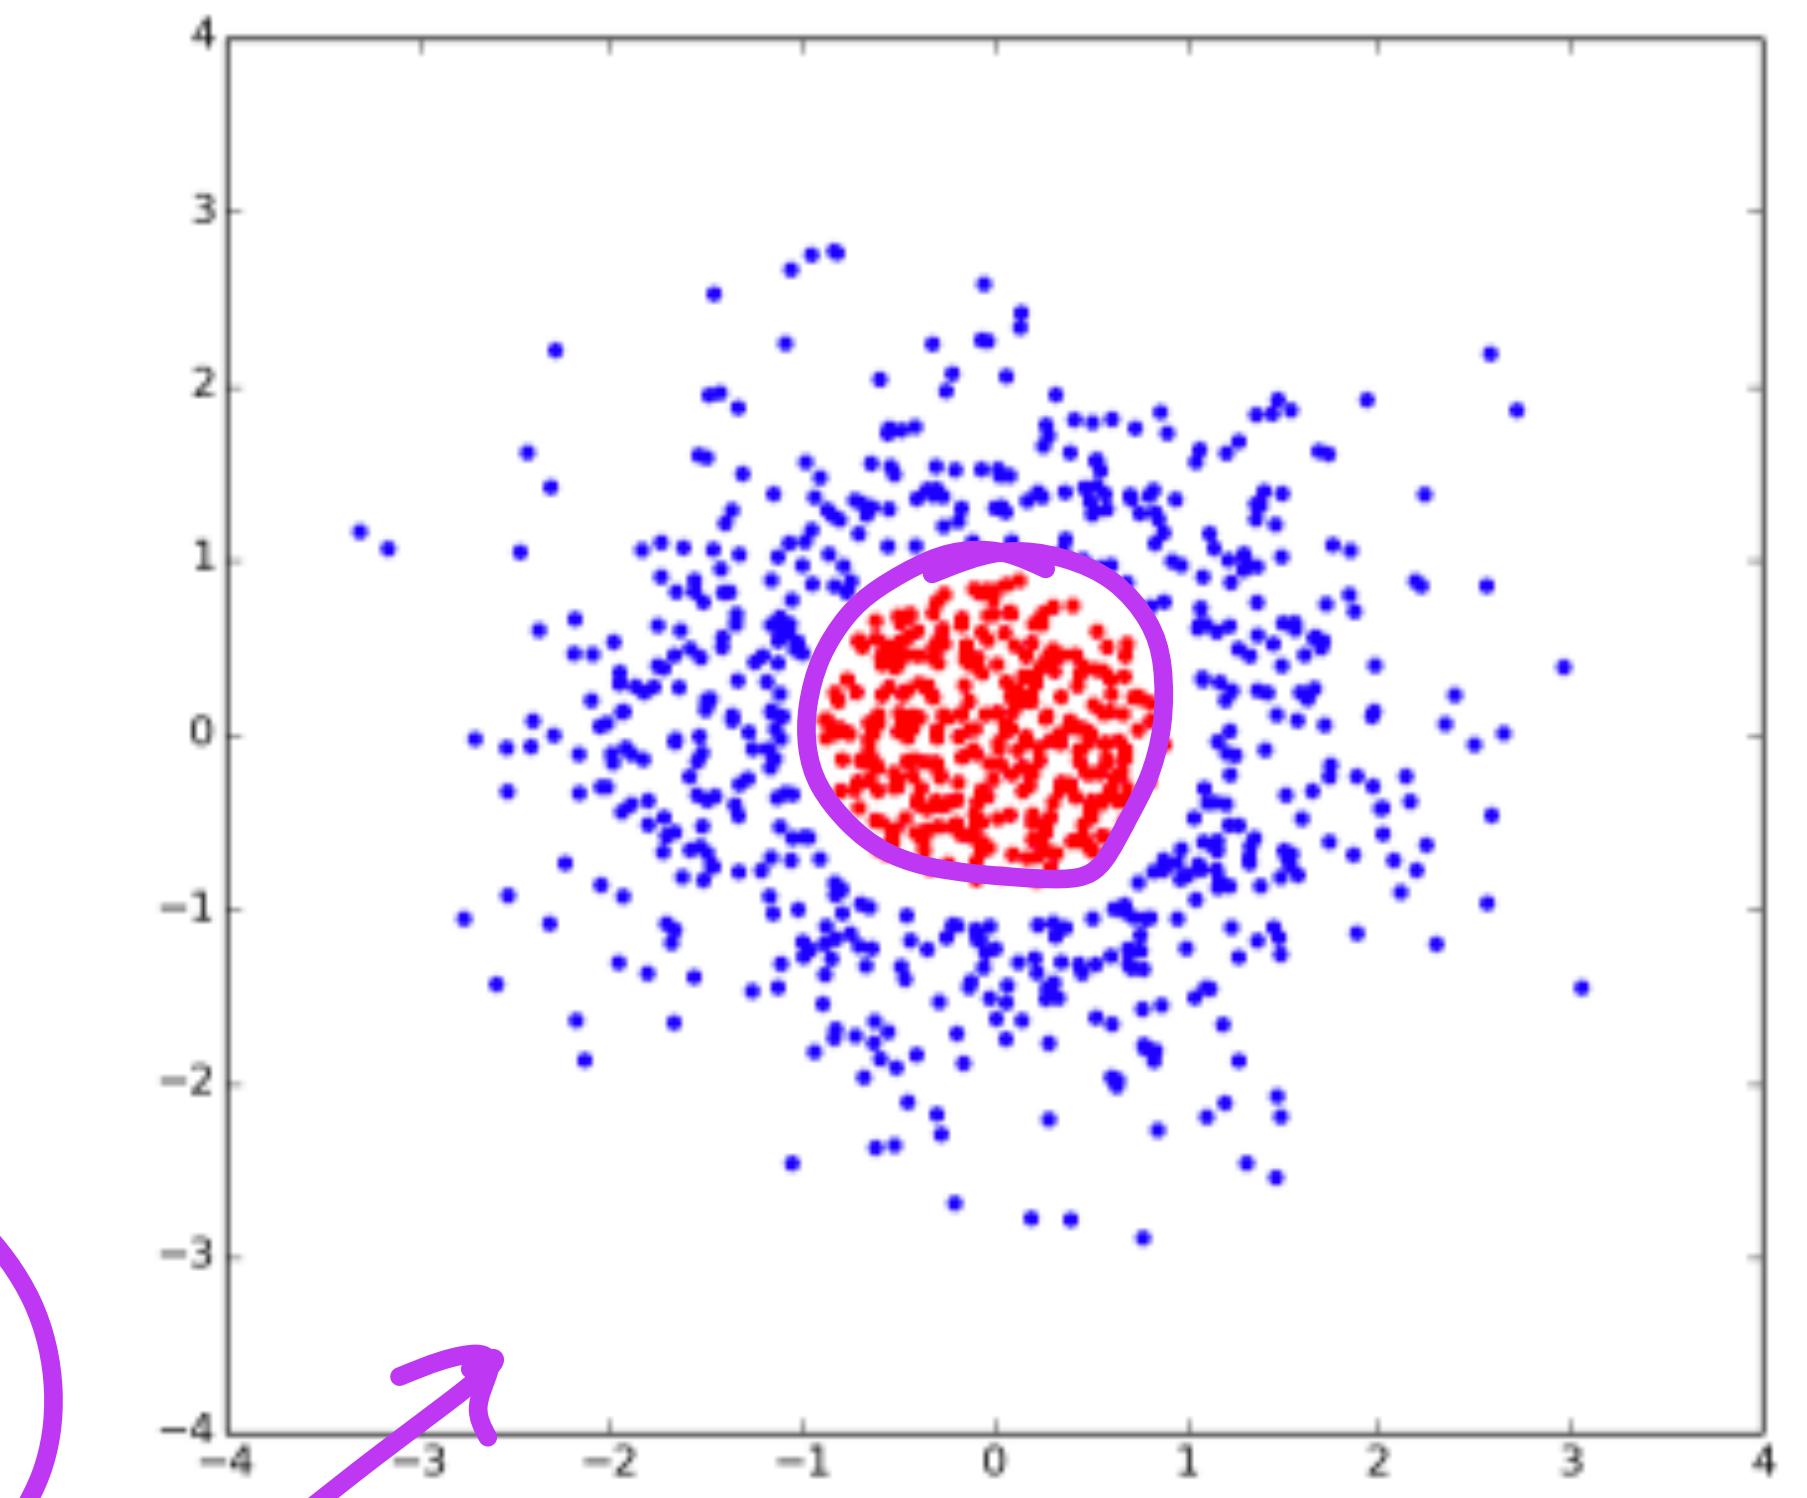

A case for neural nets

- Huge power of neural nets: $d_1: [x_1 \ x_2 \ x_3]$
 tod month geo

- they deal well with **non-linearly-separable** data

<https://www.kdnuggets.com/2016/11/quick-introduction-neural-networks.html>

<https://stackoverflow.com/questions/1148513/difference-between-a-linear-problem-and-a-non-linear-problem-essence-of-dot-pro>

$$y = mx + b$$

$$y = m\hat{x}_1 + n\hat{x}_2 + b$$

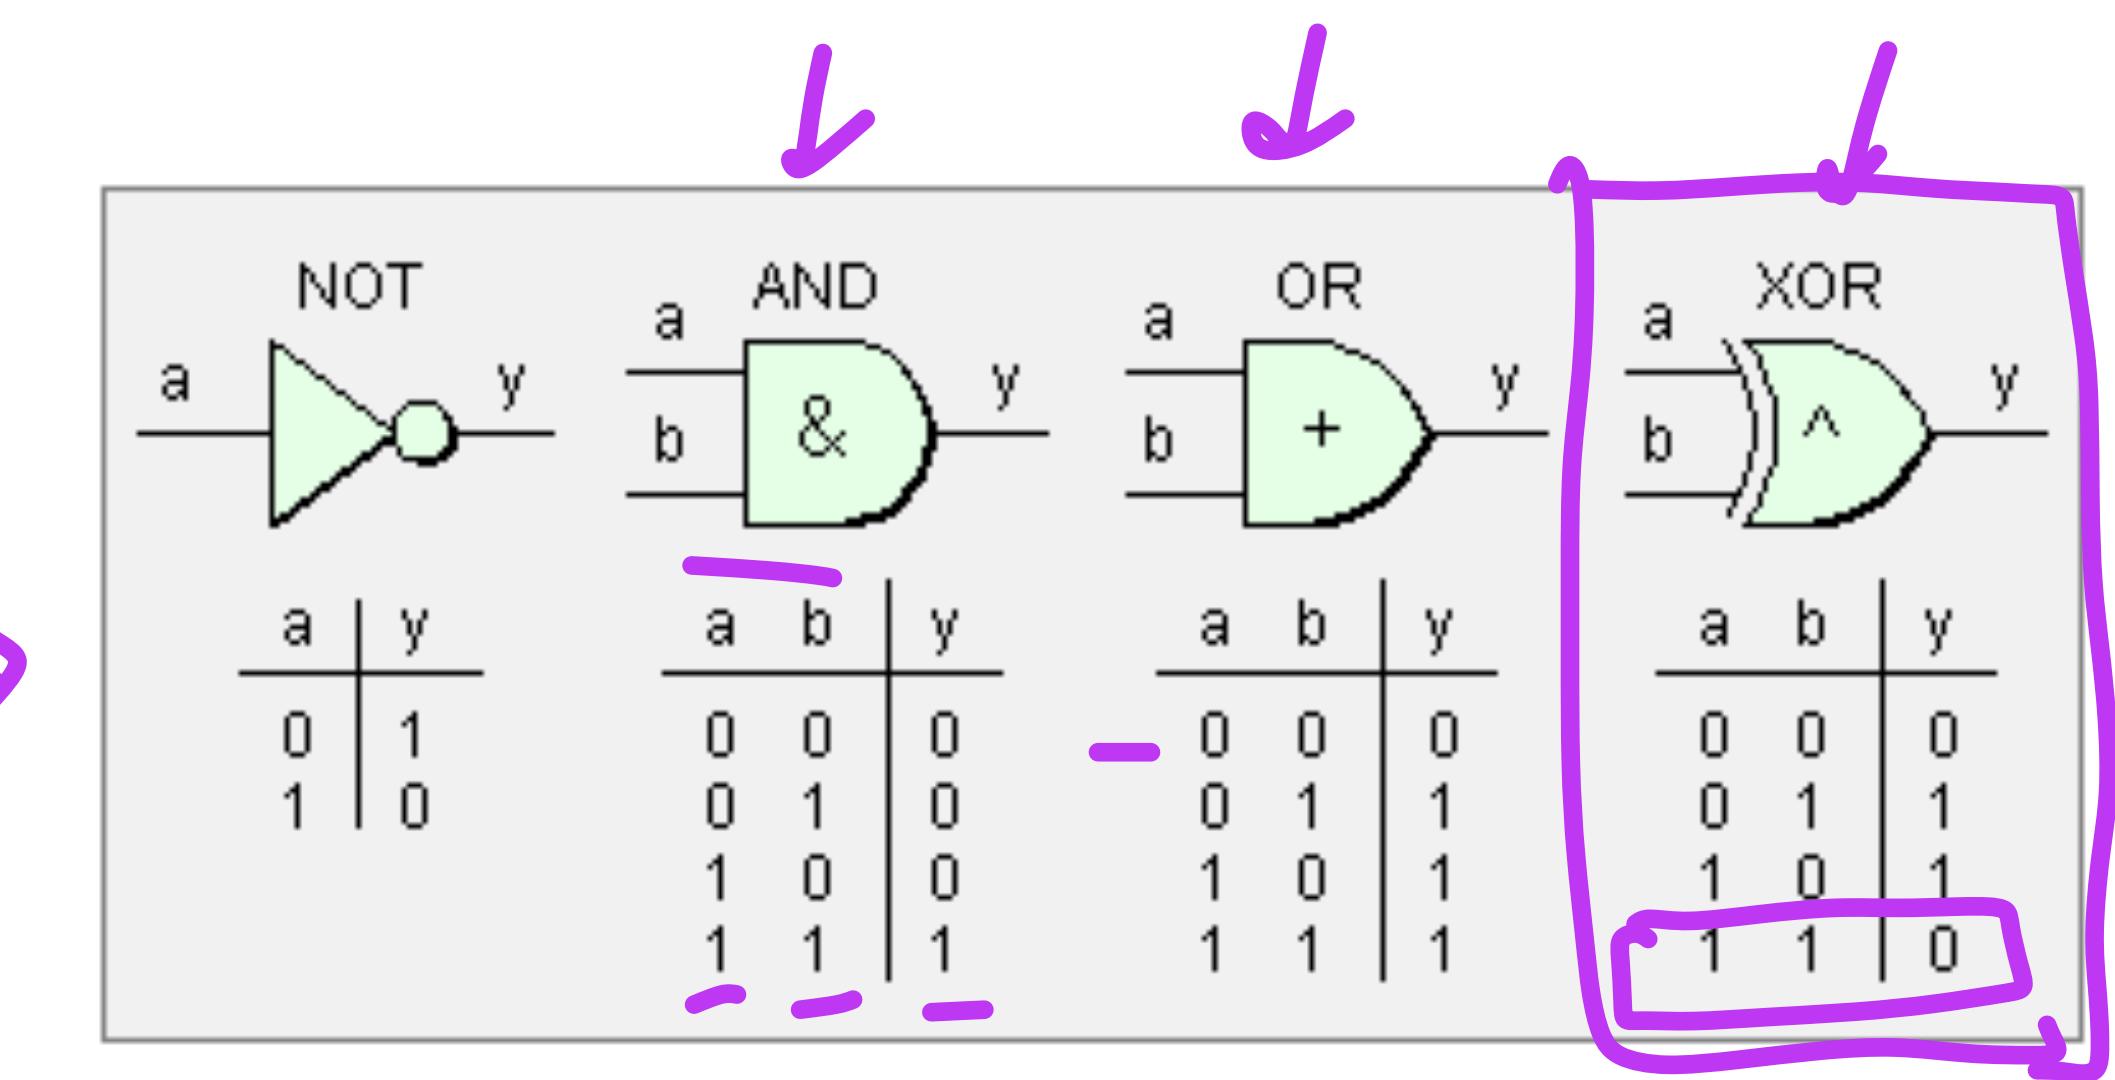

exclusive OR
XOR

$0 = \text{False}$

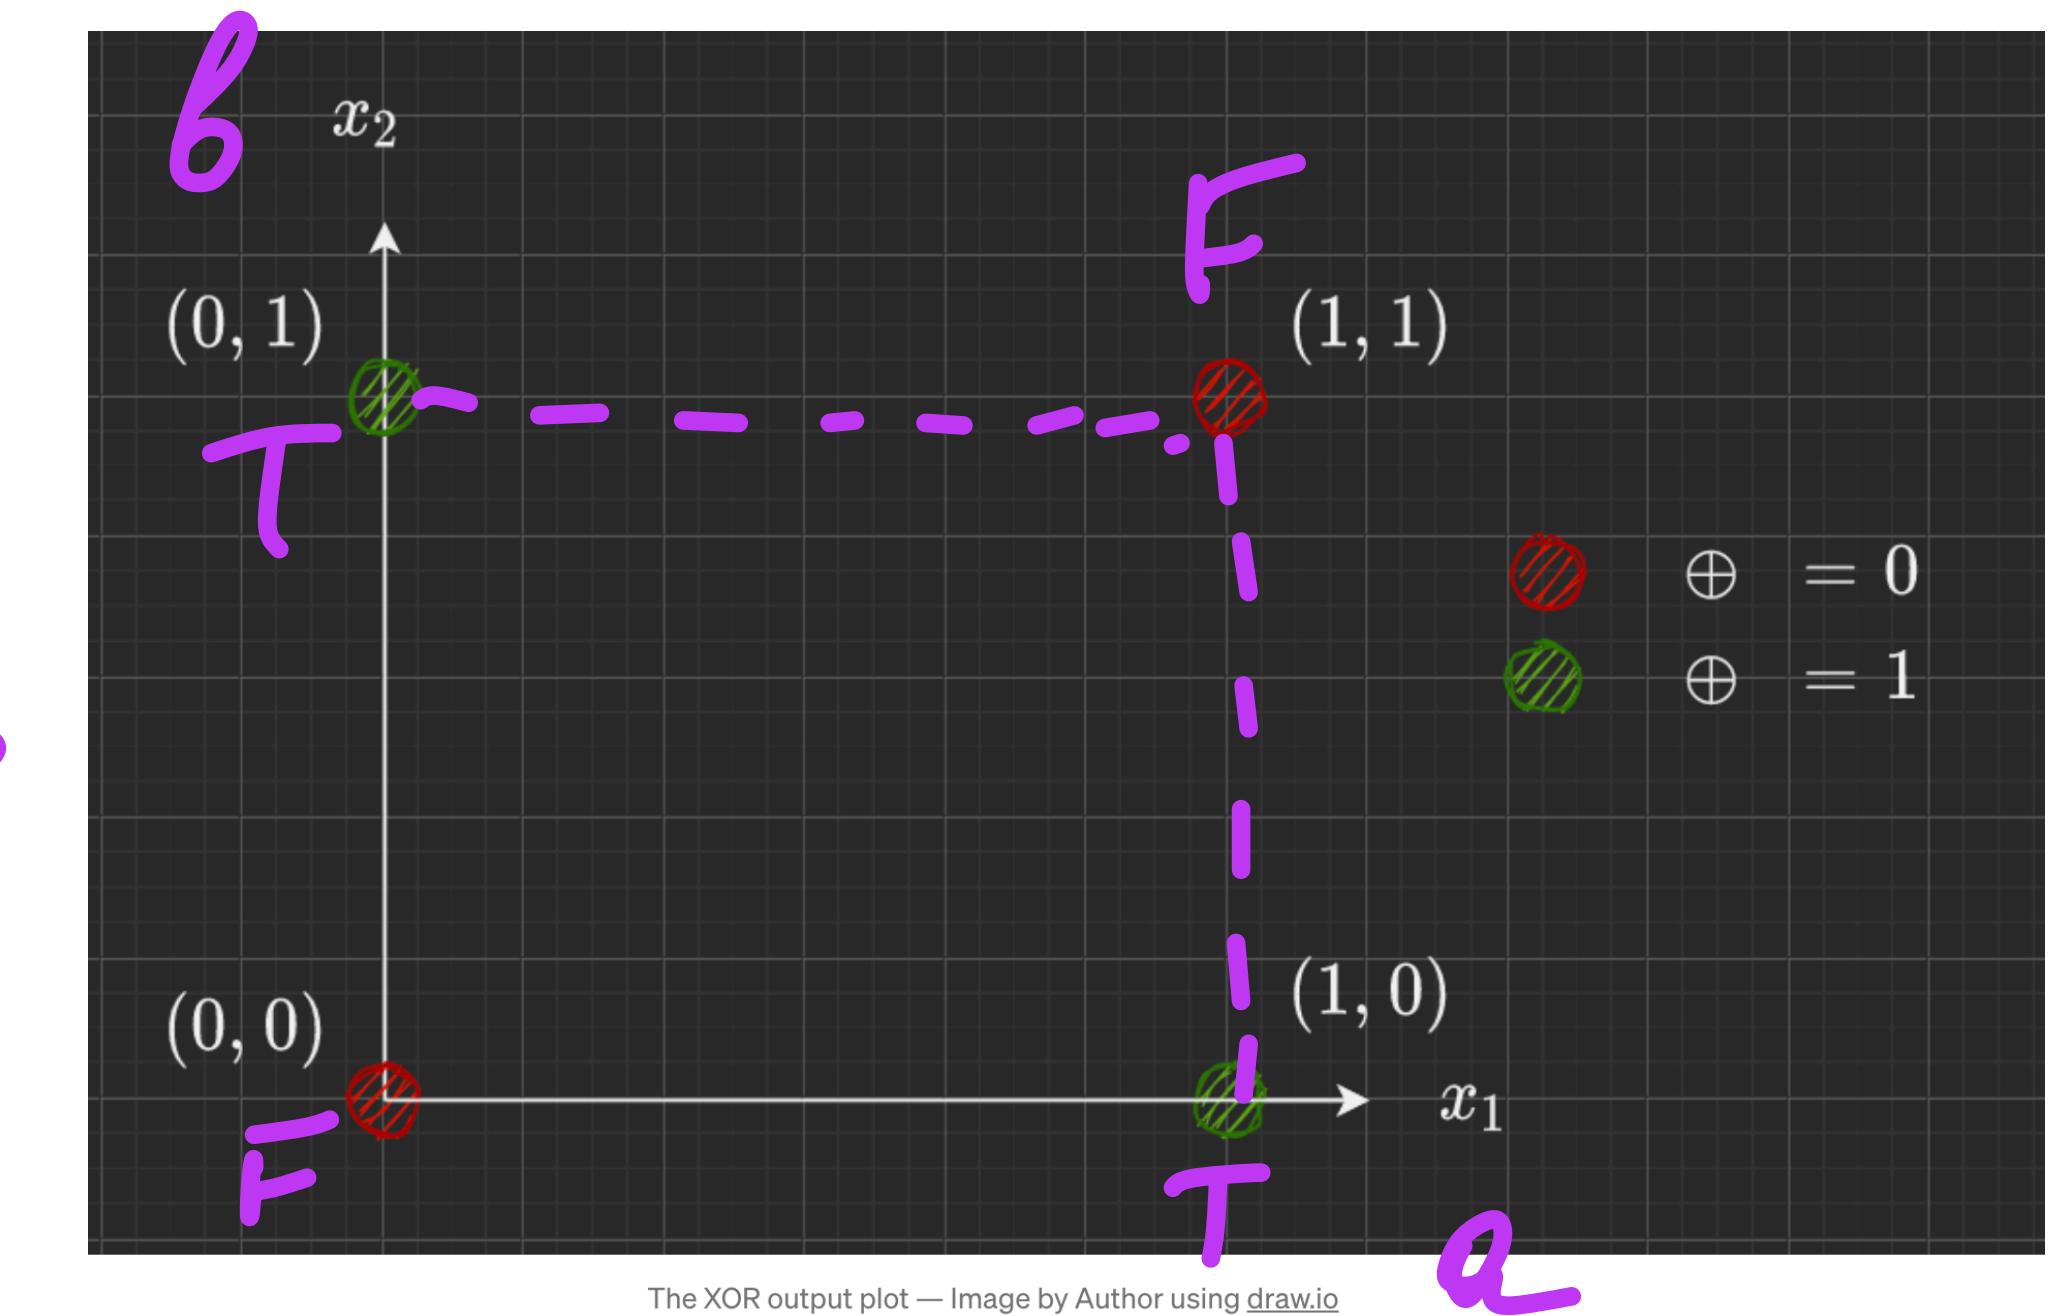

$1 = \text{True}$

A case for neural nets

- The XOR function
- Similar to our familiar **OR** in python and other programming languages
- ...but **XOR** is True **only** when **one** of the expressions is True

<https://www.eetimes.com/how-to-invert-three-signals-with-only-two-not-gates-and-no-xor-gates-part-1/>

The XOR output plot — Image by Author using draw.io

XOR

A case for neural nets

- XOR is not linearly separable
 - need a more complex decision boundary
 - The **data points** are:
 - $(0,0), (0,1), (1,0)$, and $(1,1)$
 - **(x1,x2)**
 - The output: **y** is either 1 or 0
 - True or False
 - Can we **map** x_1 and x_2 to a different space **such that** we can separate the data points linearly and correctly output the **y**?

The diagram shows four logic gates with their corresponding truth tables:

- NOT**: Input a leads to output y . Truth table:

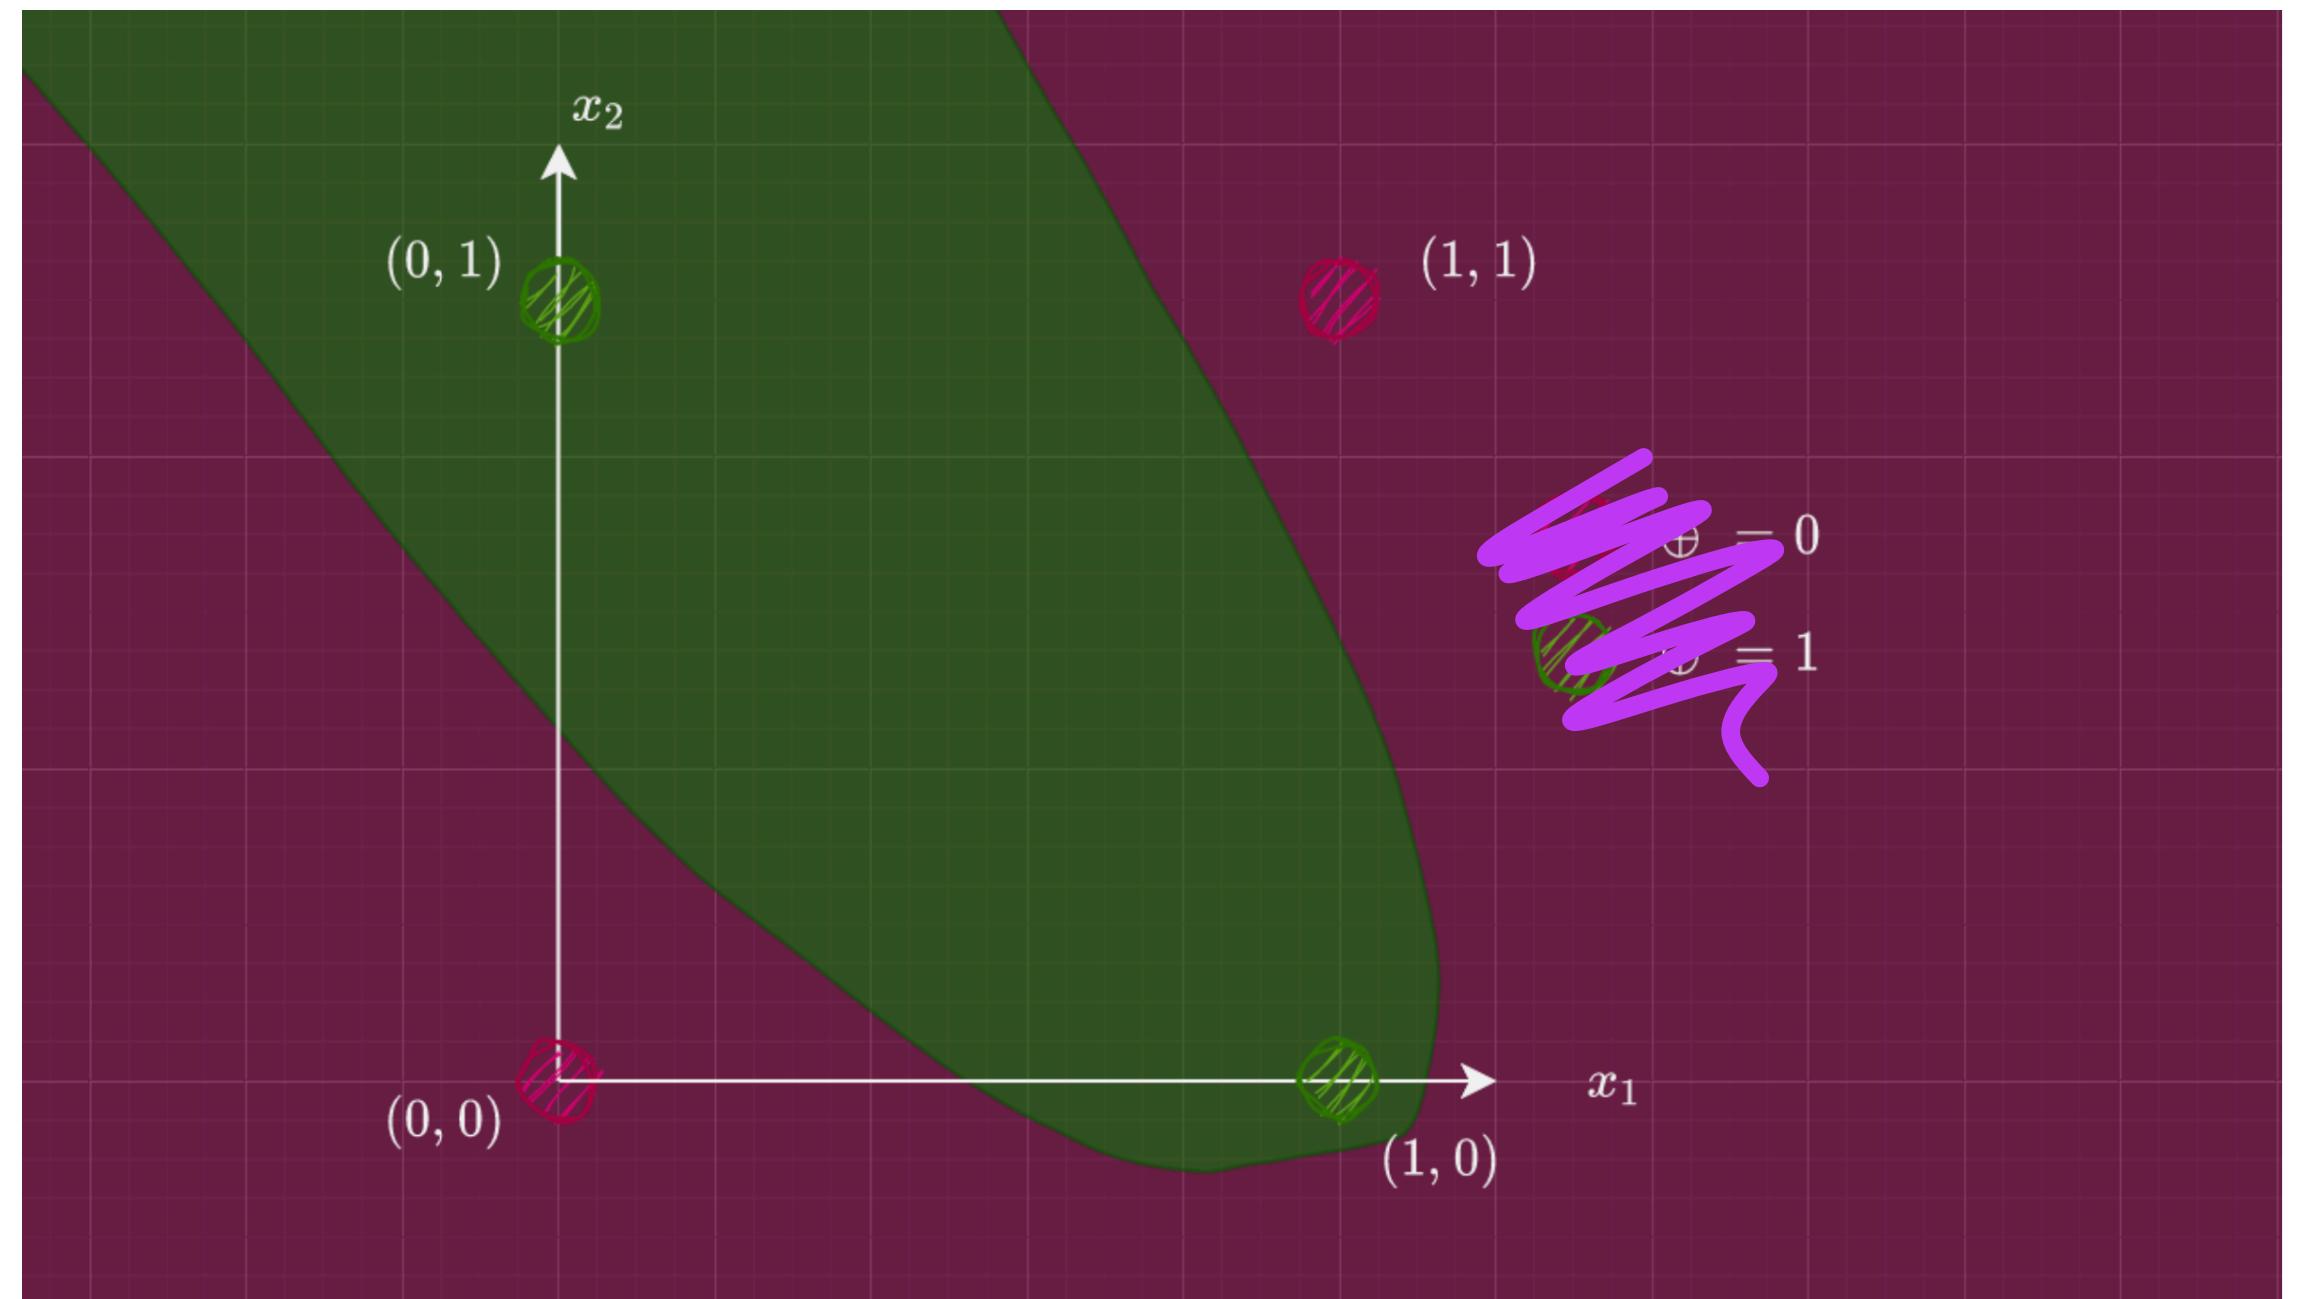

a	y
0	1
1	0
- AND**: Inputs a and b lead to output y . Truth table:

a	b	y
0	0	0
0	1	0
1	0	0
1	1	1
- OR**: Inputs a and b lead to output y . Truth table:

a	b	y
0	0	0
0	1	1
1	0	1
1	1	1
- XOR**: Inputs a and b lead to output y . Truth table:

a	b	y
0	0	0
0	1	1
1	0	1
1	1	0

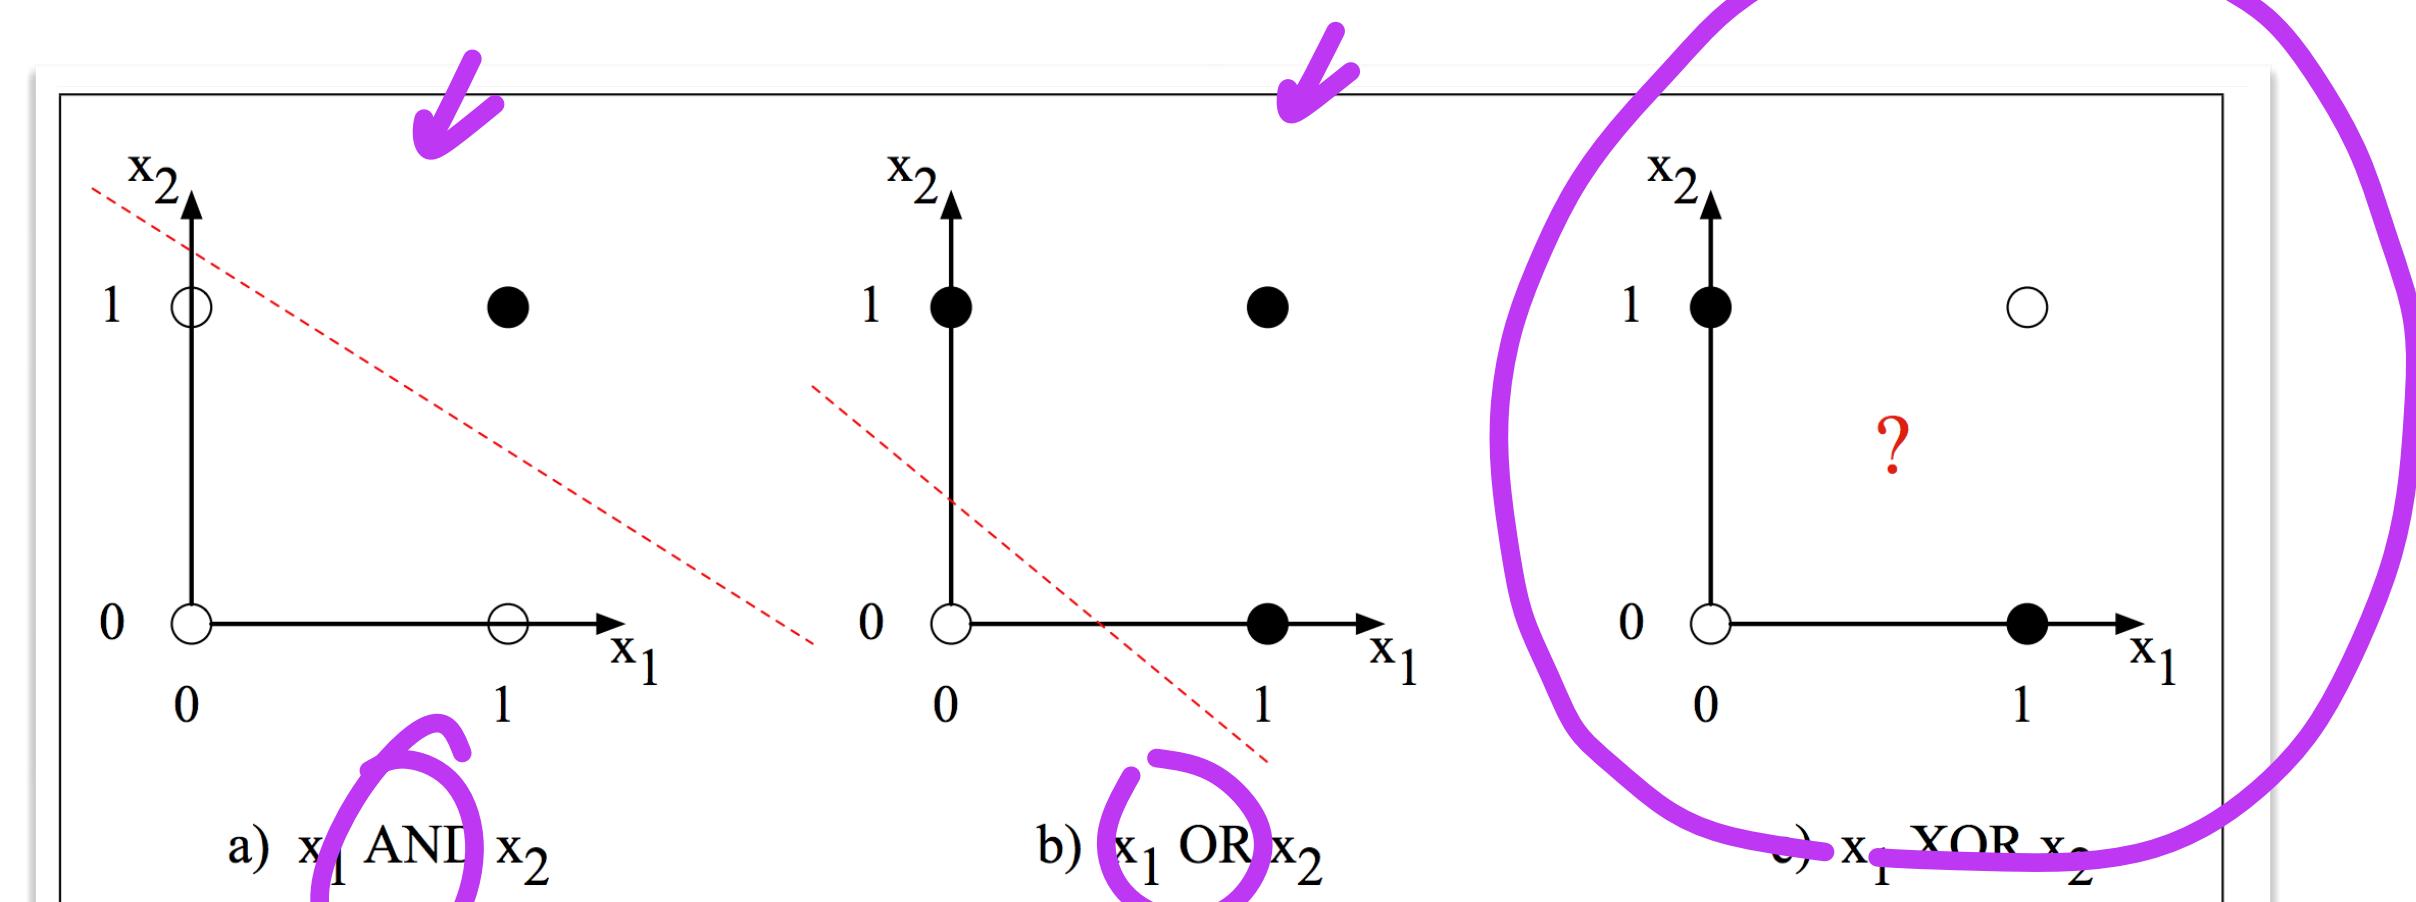

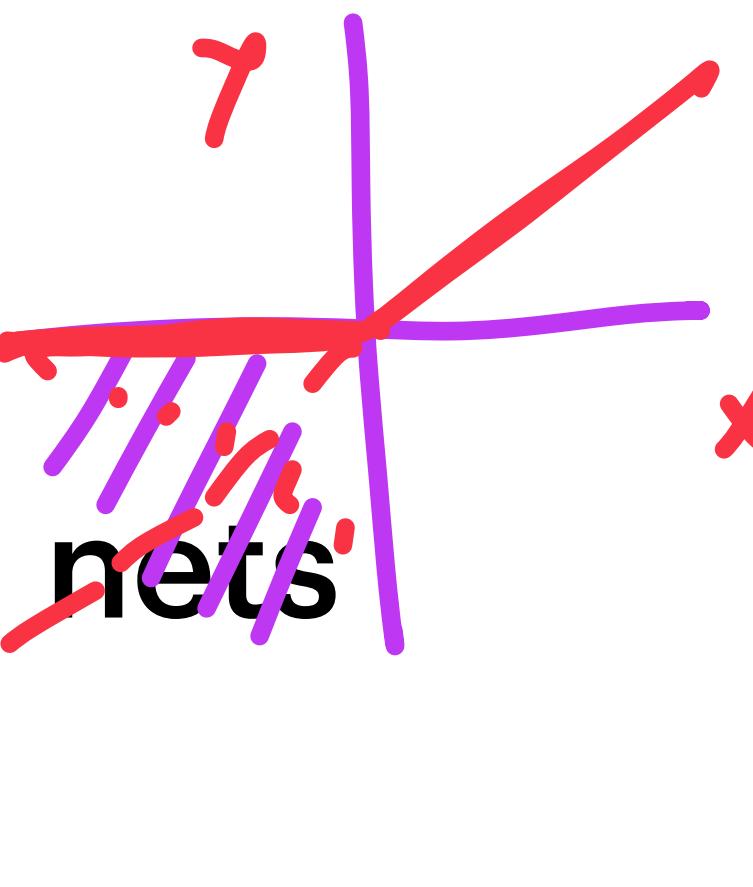

Figure 7.5 The functions AND, OR, and XOR, represented with input x_0 on the x-axis and input x_1 on the y axis. Filled circles represent perceptron outputs of 1, and white circles represent perceptron outputs of 0. There is no way to draw a line that correctly separates the two categories for XOR. Figure styled after Russell and Norvig (2002).

XOR

A case for neural nets

- Construct a simple **neural network**

- Each “neuron” is a **function**

- computes the sum of $w_1x_1 + w_2x_2 + cb$

- if result < 0: returns 0

- Each x is **weighted** upon entering each neuron

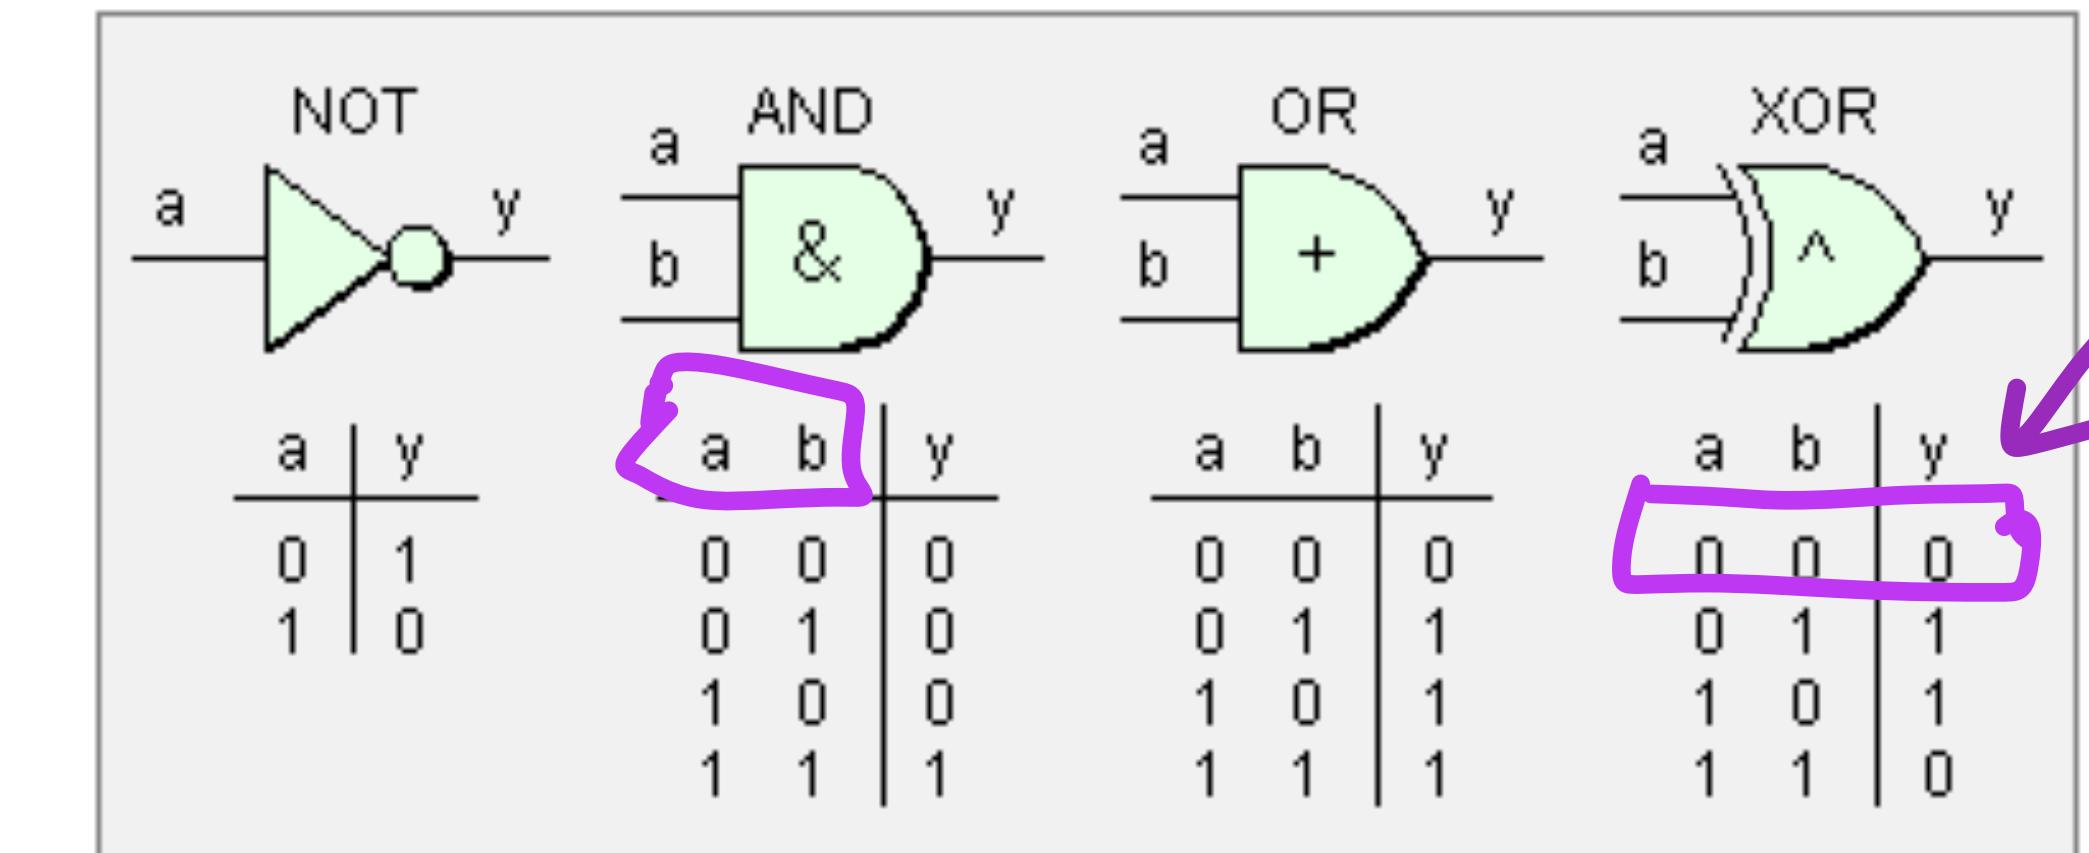

- So, like a linear equation but a network, and nonlinear :)

$$y_1 = h_1 \cdot w_{21} + h_2 \cdot w_{22} + b$$

$$y_1 = 0 \cdot 1 - 2 \cdot 0 + 0 = 0$$

$$h_2: 0 \cdot 1 + 0 \cdot 1 - 1 = -1 \rightarrow 0$$

$$\alpha = x_1 \quad \beta = x_2$$

<https://www.eetimes.com/how-to-invert-three-signals-with-only-two-not-gates-and-no-xor-gates-part-1/>

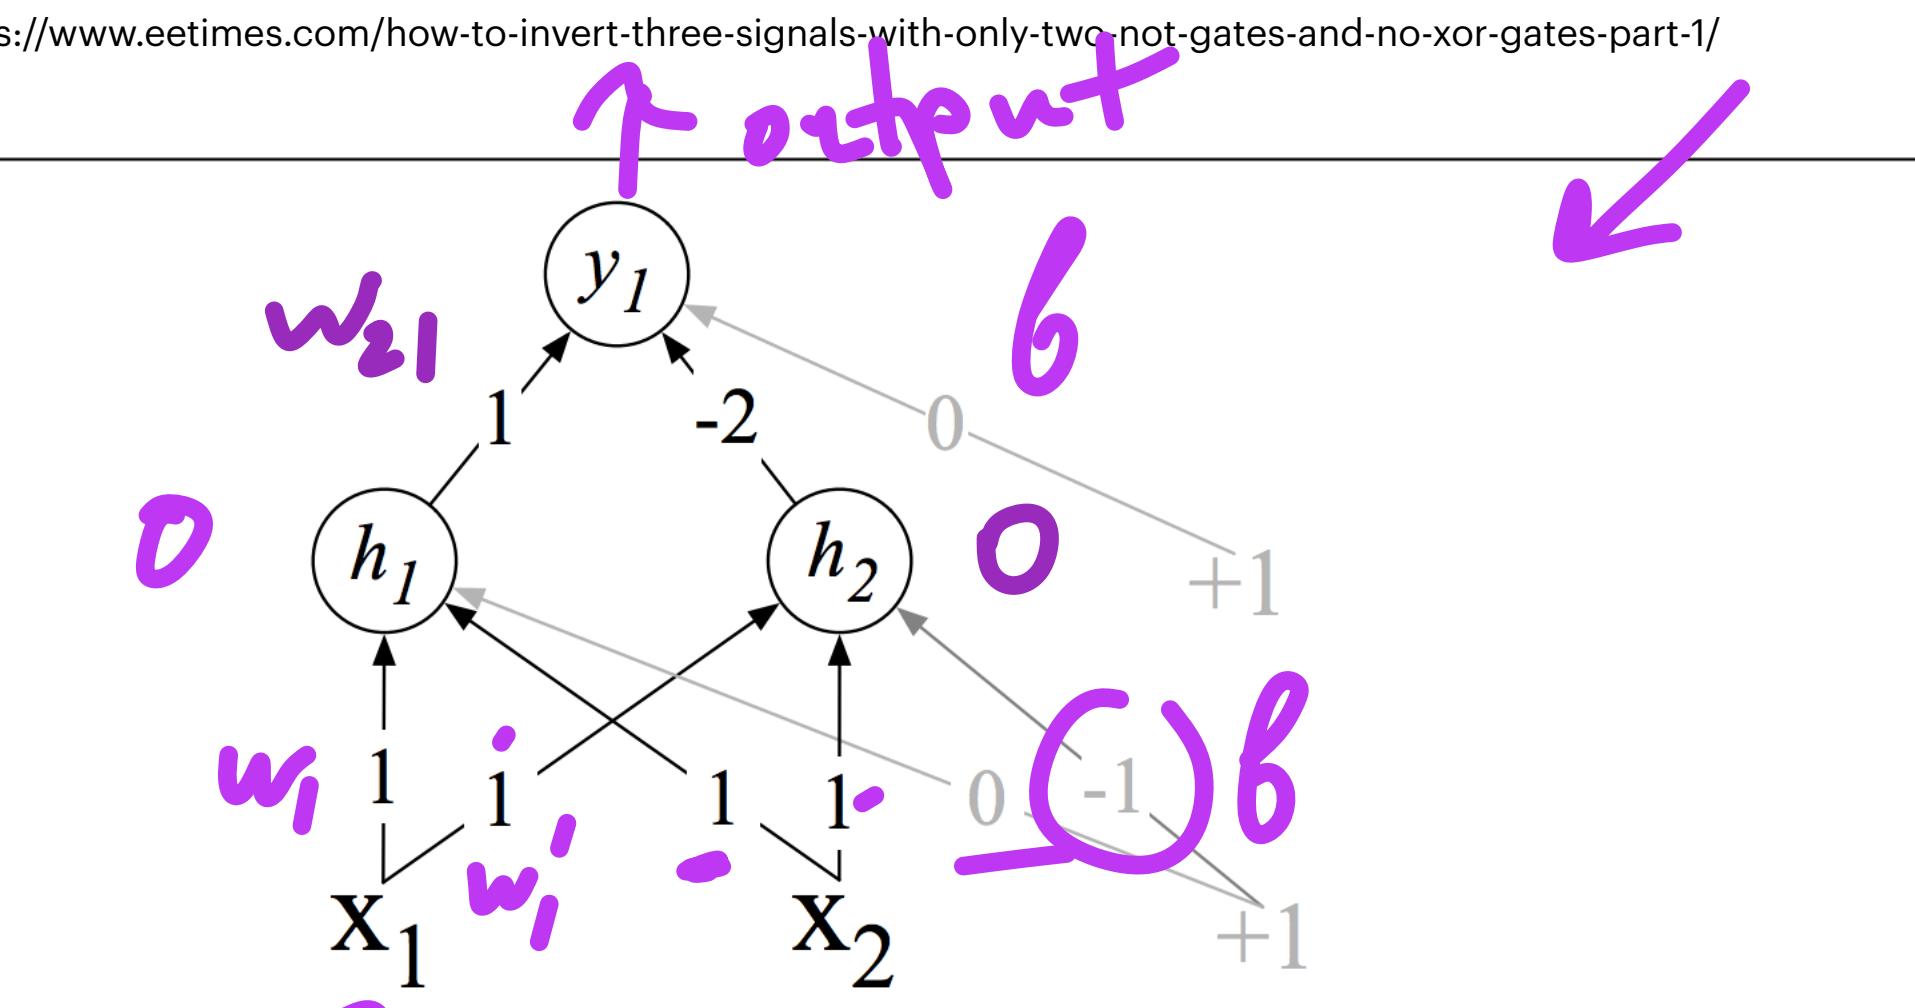

Figure 7.6 XOR solution after Goodfellow et al (2016). There are three ReLU units, in two layers; we've called them h_1, h_2 (h for “hidden layer”) and y_1 . As before, the numbers on the arrows represent the weights w for each unit, and we represent the bias b as a weight on a unit clamped to +1, with the bias weights/units in gray.

Speech and Language Processing (Jurafsky and Martin 2004)

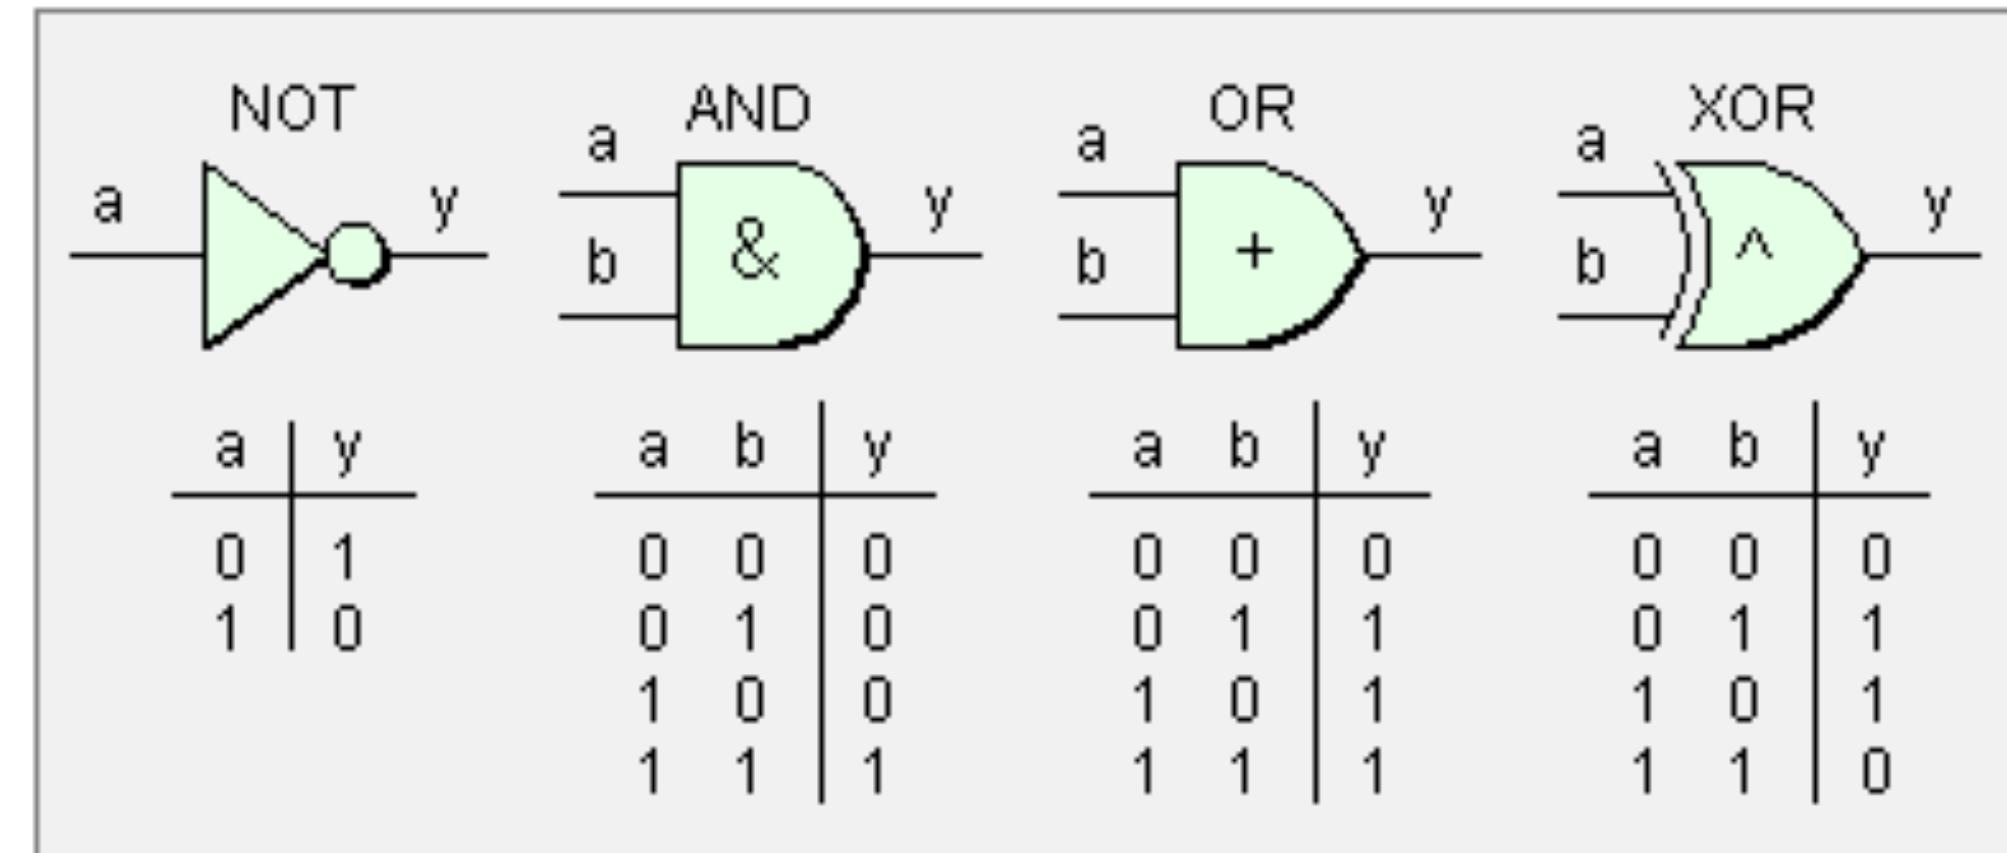

Activity (which I know you always wanted to do):
(Manually) compute the neural XOR for:
[x₁=1, x₂=1] and [x₁=1, x₂=0]

<https://olzama.github.io/Ling471/assignments/activity-May18.html>

XOR

A case for neural nets

- Our x_1 and x_2 :
 - now turned into h_1 and h_2
 - ...which exist in a different space
 - ...and are linearly separable

<https://www.eetimes.com/how-to-invert-three-signals-with-only-two-not-gates-and-no-xor-gates-part-1/>

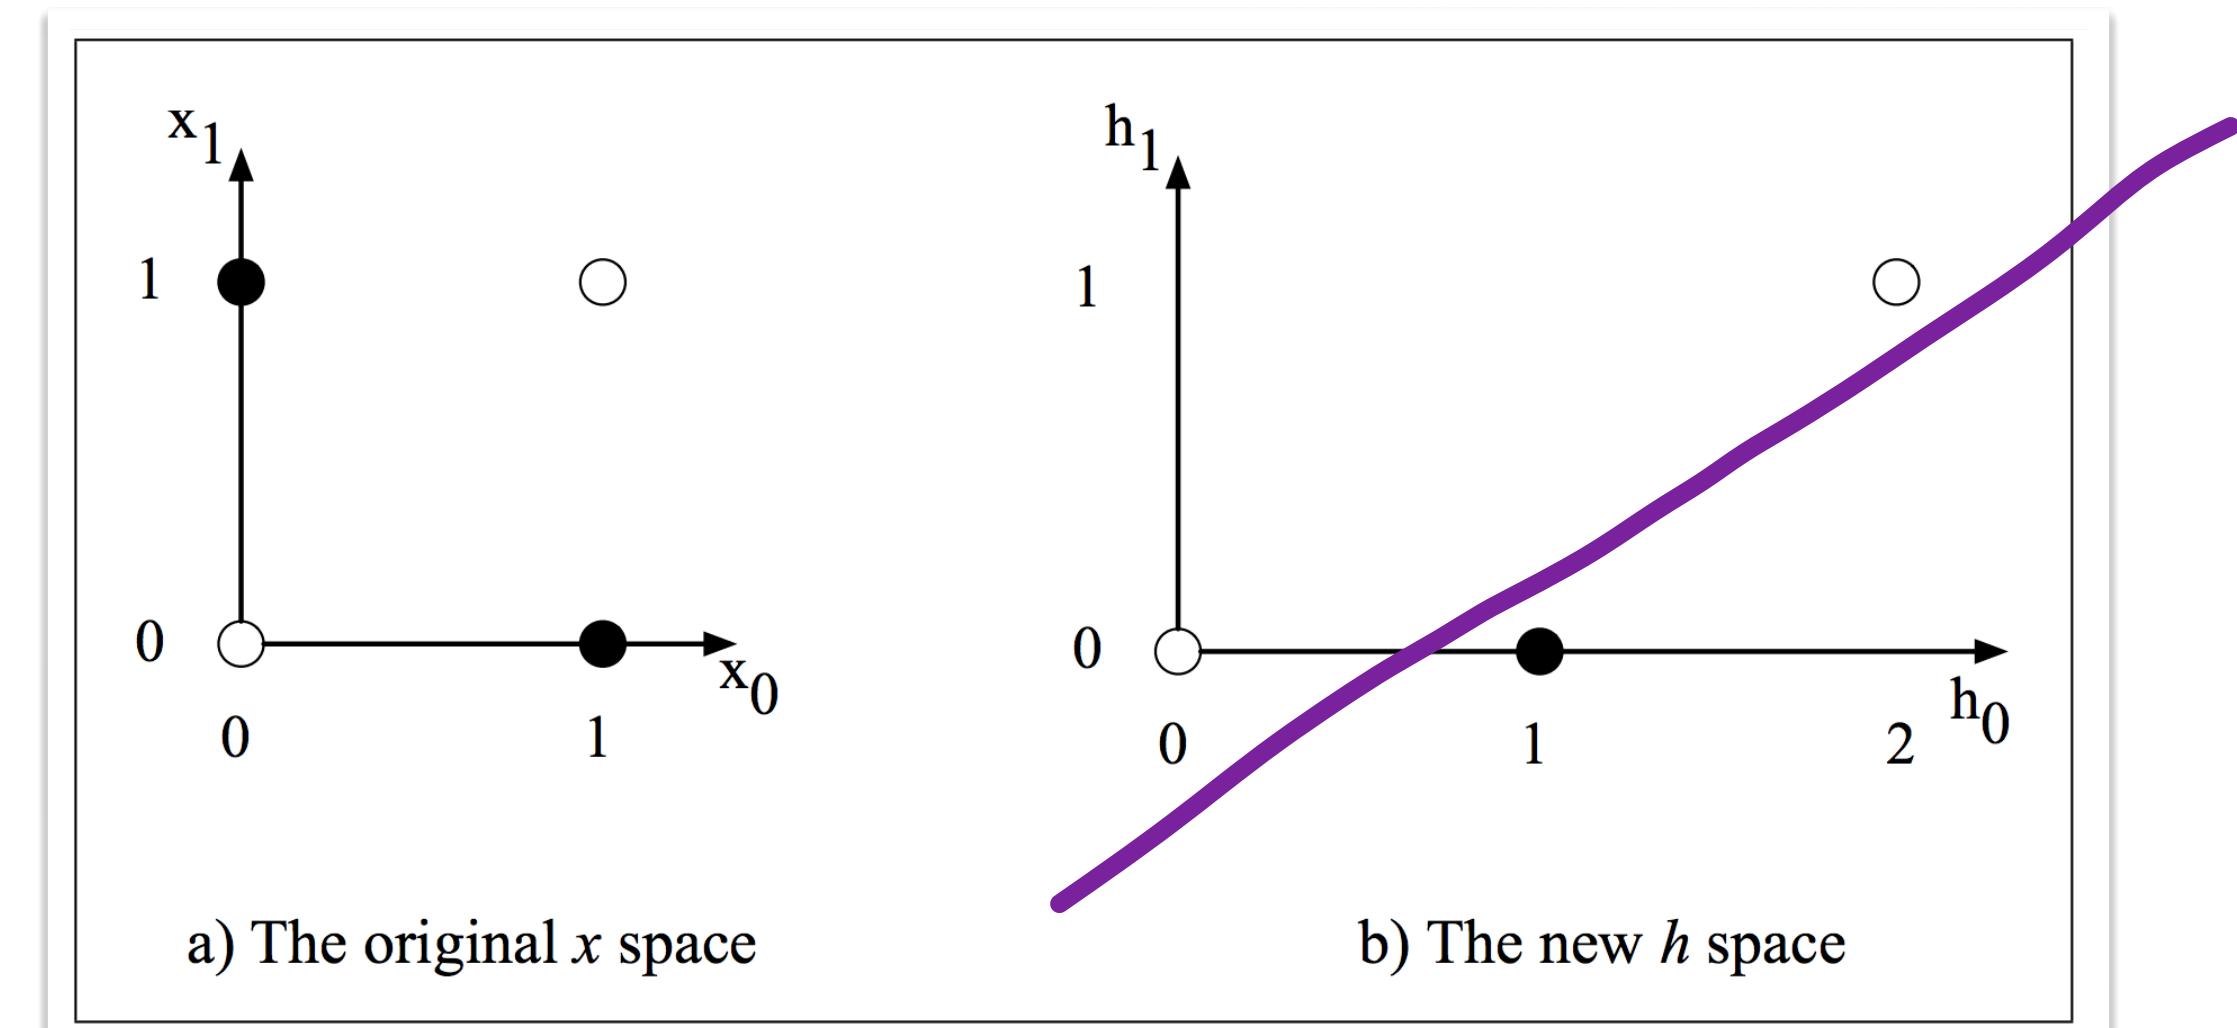

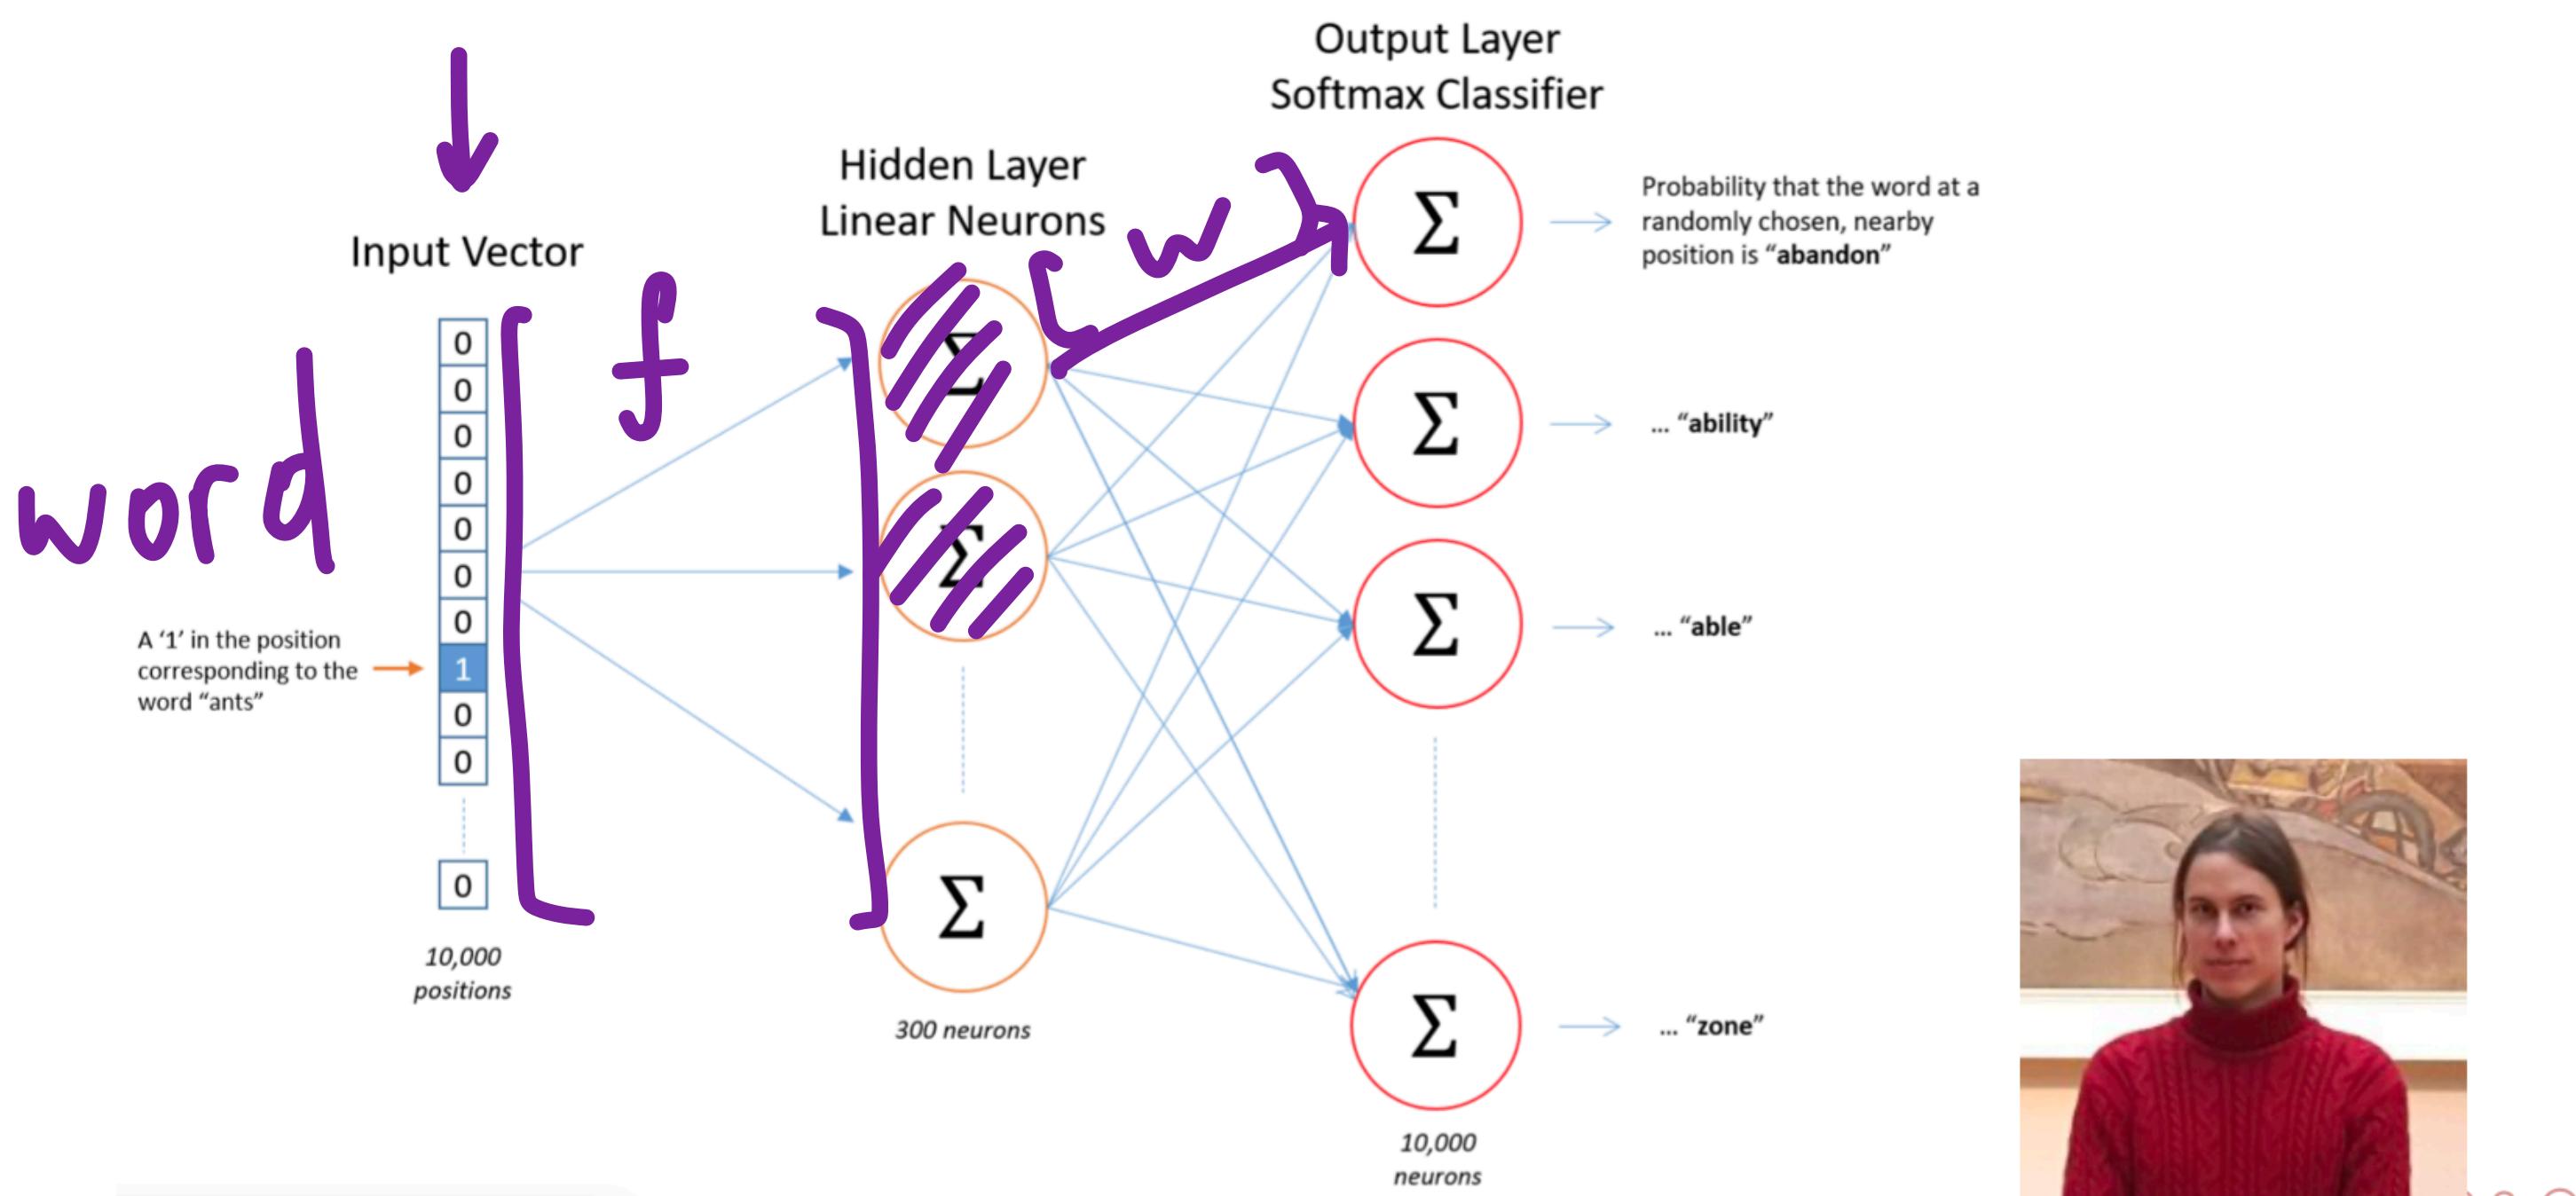

Figure 7.7 The hidden layer forming a new representation of the input. Here is the representation of the hidden layer, h , compared to the original input representation x . Notice that the input point $[0 \ 1]$ has been collapsed with the input point $[1 \ 0]$, making it possible to linearly separate the positive and negative cases of XOR. After Goodfellow et al. (2016).

(Simplified) neural models architecture

V

- ▶ The *feed-forward* SkipGram model (Mikolov et al)
- ▶ Input: a word from the vocabulary
- ▶ Middle: two matrices and some matrix multiplication
- ▶ Output: a probability for each word in the vocabulary occurring *somewhere nearby* the input word

- What are the “two matrices”?!

Pic from: <http://mccormickml.com/2016/04/19/word2vec-tutorial-the-skip-gram-model/>
